1.0 INTRODUCTION

The purpose of this report is to provide detailed design information related to the storm drainage and stormwater management (SWM) plan, sanitary and water servicing for the proposed development at 128 Lakeshore Road East, generally west of Hurontario Street in Mississauga. This report will demonstrate the stormwater management measures that will be undertaken to deal with water quantity and quality, the proposed sanitary and water servicing, as well as erosion and sediment control during construction.

1.1 Site Description

The site is located on the north side of Lakeshore Road East, west of Ann Street, generally west of Hurontario Street. The total site area is 930m² and has an existing two-storey building that is to be demolished. Refer to **Figure 1** for the site location.

A eight-storey mixed use residential building is proposed for the site, with one level of underground parking as well as landscaping.

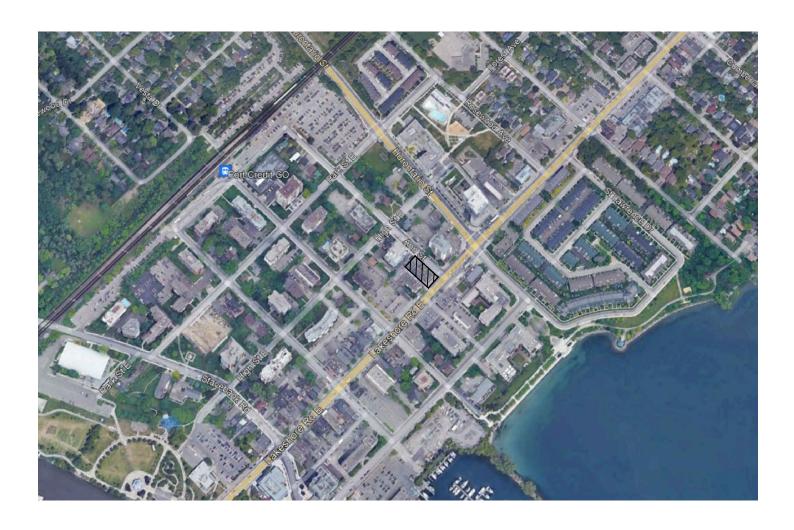

1.2 Background

Water and sanitary connections are proposed to meet the functional needs of the site and to meet the requirements of the Region of Peel. The SWM plan has been designed to meet the requirements of the City of Mississauga (The City) and Credit Valley Conservation (CVC). The following materials were referenced in the preparation of this report.

- The City of Mississauga Development Requirements Manual (DRM), updated and effective January 2020.
- The <u>Stormwater Management Planning and Design Manual (MECP Guidelines)</u>, prepared by the Ministry of the Environment, March 2003.
- The <u>Erosion & Sediment Control Guideline for Urban Construction</u>, prepared by the Greater Golden Horseshoe Area Conservation Authorities (GGHA CA), December 2006.
- As-constructed plan and profile drawings for Lakeshore Road and Ann Street, provided by the City and Region.

The proposed SWM scheme has been prepared to meet the City's requirements. Refer to **Appendix A** for the background information.

LEGEND

SITE LOCATION

FIGURE 1 128 LAKESHORE ROAD EAST SITE LOCATION PLAN

DATE: AUGUST 2025 SCALE: N.T.S. PROJECT: 211246

2.0 DESIGN CRITERIA

The following design criteria have been followed in the preparation of the grading, servicing and Stormwater management on the site.

- The DRM requires retention of water on site, to the extent possible, to match predevelopment runoff volumes. This requirement is typically achieved by retaining the runoff from a 5mm 24-hour storm on-site, which is equivalent to approximately 50 percent of the total average rainfall volume.
- Water quality controls are required to achieve enhanced water quality control, which requires an 80 percent total suspended solids (TSS) removal level.
- The downstream sewer is at capacity based on discussions with the City, so over-control of the flows onsite to levels below the existing condition is required.
- Provide an erosion and sediment control plan following the Erosion & Sediment Control Guidelines for Urban Construction, prepared by the Greater Golden Horseshoe Area Conservation Authorities (GGHACA), December 2006.

The proposed design has been prepared following these criteria.

3.0 SITE DRAINAGE

All grading will be completed in a manner to satisfy the following goals:

- Maintain sufficient sight lines and existing road gradients.
- Enable gravity servicing connections to the existing sewers on Lakeshore Road.
- Not adversely impact adjacent private properties.
- Achieve stormwater management and environmental objectives required for the site.

The proposed grading of the site has been designed to meet these requirements. Refer to **Drawing C100** for the proposed site grading design.

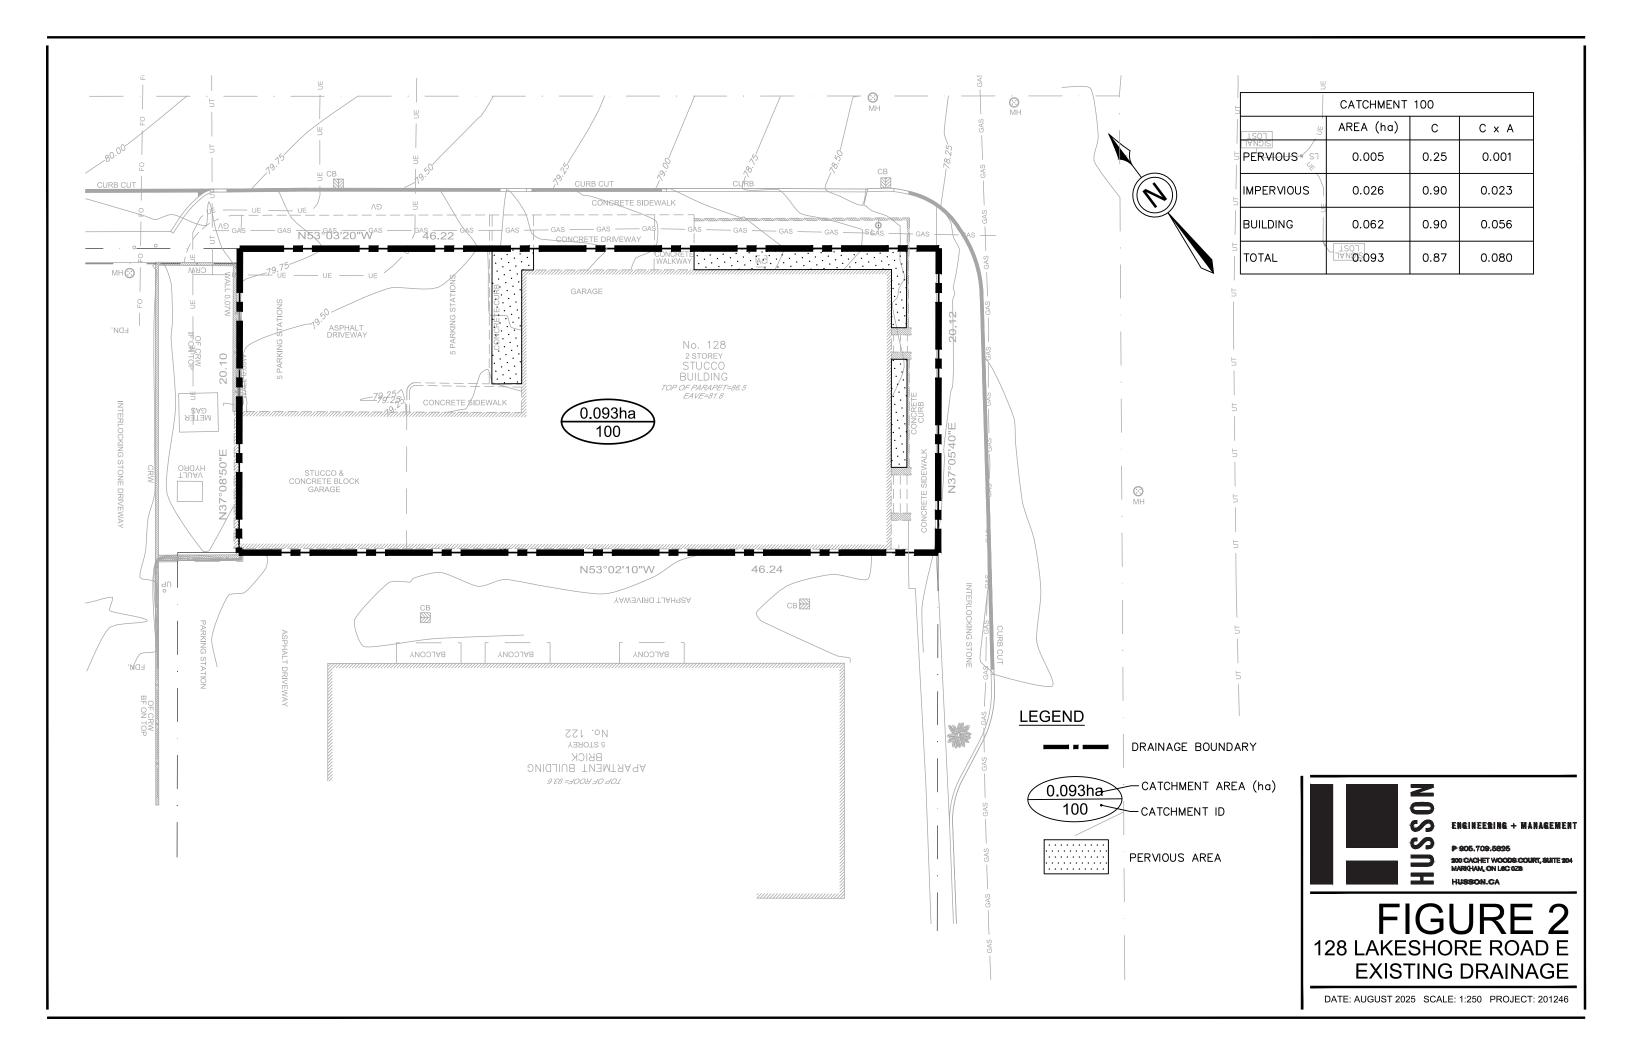

3.1 Existing Drainage

There is an existing 1650mm diameter storm sewer on Lakeshore Road East to the south of the site. There is no storm sewer adjacent to the site on Ann Street. The majority of the existing site generally drains towards Lakeshore Road East. Refer to **Figure 2** for the existing site drainage.

The design of the site is proposed to generally maintain the existing drainage patterns, and outlet at the south to the existing MH.

3.1.1 Target Flows

The existing site runoff coefficient is 0.87 to Lakeshore Road East. In order to reduce the contribution from the site based on the capacity issues identified by the City, the target is based on controlling all flows up to and including the 100-year event to the 10-year event with a Runoff Coefficient of 0.50.

Therefore, the post development flows will be less than the existing condition, as required. **Table 1** summarizes the target flows for the site.

Table 1. Target Flows

Existing Site	Catchment Area	Runoff Coefficient	Target Flow Rate	
(Storm Event)	(m²)		(L/s)	
10 Year	930	0.50	12.8	

The proposed design was completed to provide controls for all storm events up to the 100 year storm to meet the target flow rates from the site, as outlined following. Refer to **Appendix B** for the stormwater management calculations.

3.2 Minor System Drainage

The internal storm sewer system will be designed to collect drainage from the building for a 100 year design storm. The system will drain through the building to a cistern located on the basement level.

The controlled flow will be directed to the control MH at the southern portion of the site. There is a small portion of the site, around the perimeter to the south and east, that will direct flows uncontrolled to the Lakeshore Road East Right of Way as a result of grading constraints on the site.

The proposed servicing can be referenced on **Drawing C101**, and the grading design is shown on **Drawing C100**.

4.0 STORMWATER MANAGEMENT PLAN

A stormwater management plan has been prepared for the site following the DRM and MECP Guidelines, to meet the stormwater management criteria for the site. Low-Impact Development (LID) techniques were investigated for the site, including the use of infiltration measures.

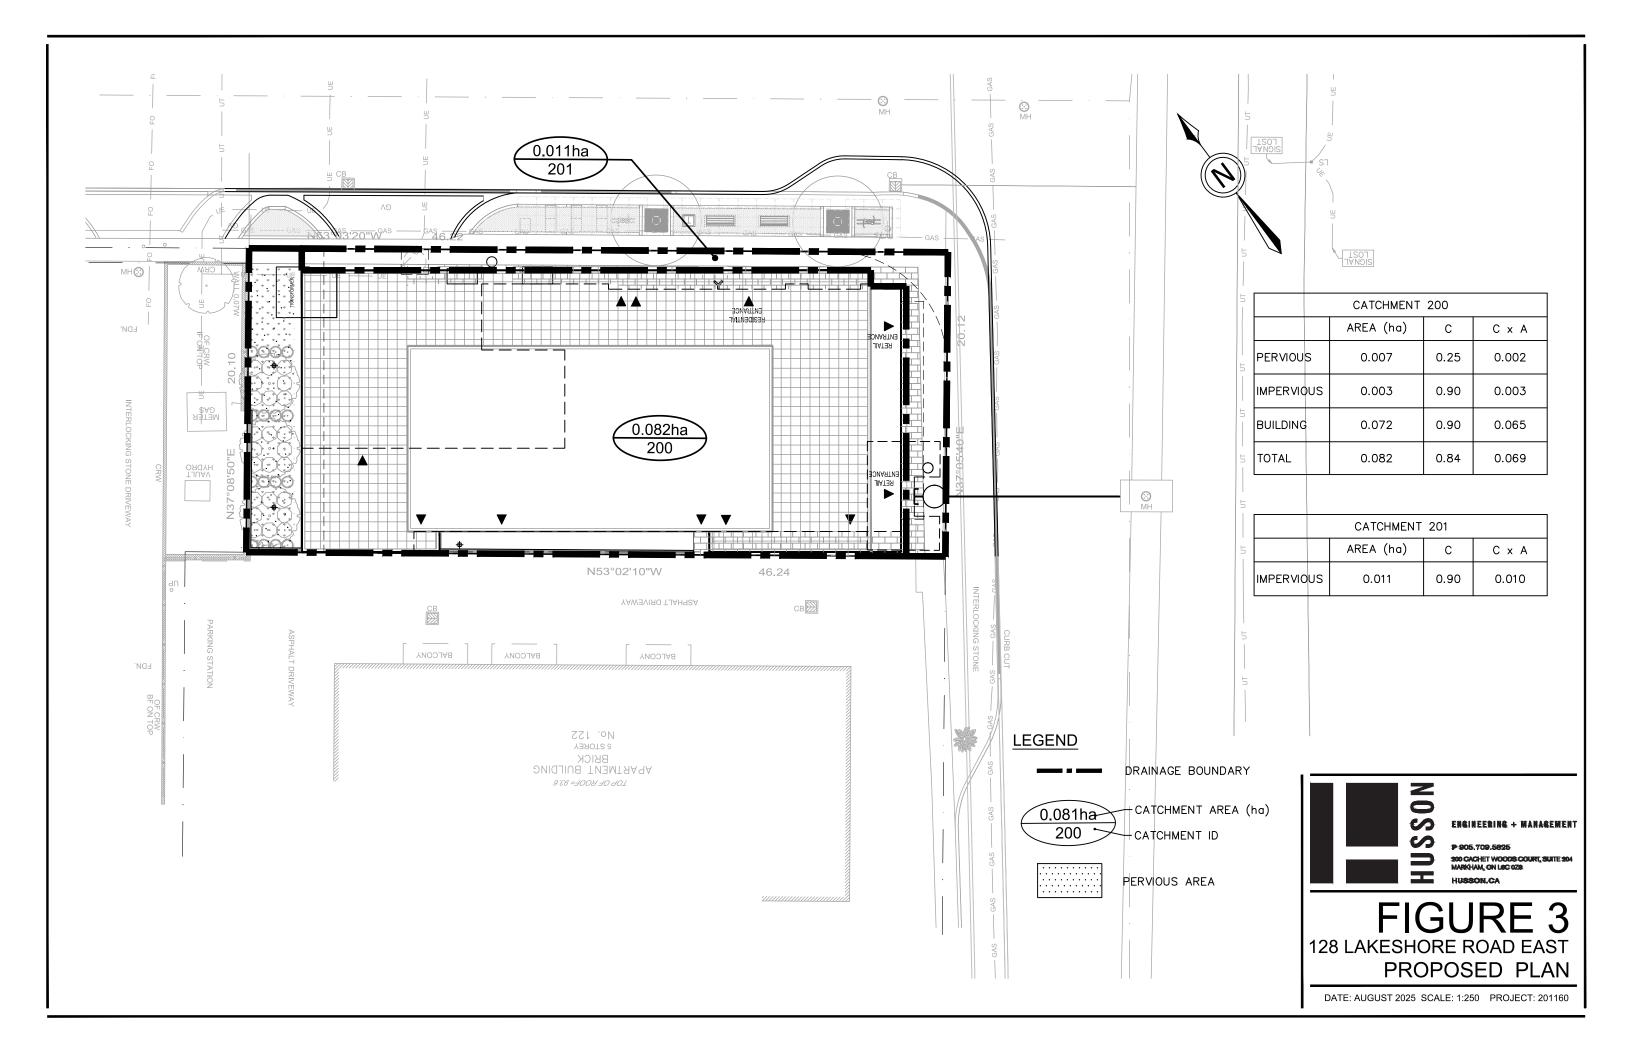

4.1 Water Balance

As per the DRM erosion design criteria, retention of runoff from a 5mm design storm on-site is required.

The required retention volume is 4.65m³ (930m² x 5mm). A variety of options are discussed following that could potentially be used to meet the target storage volume.

Permeable Pavement – The surface area could be paved with Permeable Interlocking Concrete Pavers. These are pre-cast pavers that permit water to infiltrate between the paving stones into a clear stone storage reservoir. A permeable pavement with a stone reservoir could be considered a dry-well and, therefore, must be located a minimum of 5m from the building foundation, as per OBC requirements. With the size of the proposed development, this is not feasible for the site.

Green Roof – Green roofs offer water resource benefits such as water quality, water balance and peak flow controls, in addition to other benefits including improved energy efficiency and reduced heat from the rooftop. However, a green roof is not proposed for the building.

Grassed Swales – Grassed swales are used to provide additional water quality controls for surface water, but in this case, the impact would be negligible and not provide sufficient treatment given the limited landscaping proposed on the site. Therefore, this measure is not proposed for this development.

Bioretention – This is a facility that temporarily stores and infiltrates water. Quality treatment is provided by plant material and by filtration through the bed material, which consists of a mixture of sand, fines and organic material. The roof drainage could be routed to a bioretention swale, and stormwater from frequent storms could be infiltrated. However, this is not feasible for this project, given the limited landscaped area on site.

Underground Storage – Storage could be provided in an underground system surrounded by clear stone for infiltration. Storage is provided in both the chambers as well as in the voids within the clear stone, below the outlet invert of the system, so that the required retention volume will only discharge via infiltration. However, infiltration is not feasible for the site due to the minimum 5m separation from the building foundation.

For storms up to the 100-year event, the roof area drains of the proposed building will route drainage to the cistern. Retention will be provided below the outlet invert of the proposed cistern. The total required retention volume is approximately 4.65m³. It is anticipated that best efforts will be made to re-use this volume on the site through landscape irrigation and other internal measures as feasible, to be confirmed during the detailed design stage.

4.2 Quality Control

Based on the DRM, the water quality criterion for this site is 80 percent average TSS removal from runoff originating onsite. The majority of the site is rooftop or landscaped which produces clean runoff. The split is approximately 77% rooftop area, 23% ground area.

The quality control requirements for the site can be addressed through a combination of the roof and other on-site landscape measures. Overall TSS removal capabilities are based on the following assumptions:

- Rooftop and terraces runoff is generally clean and credited with 80 percent TSS removal.
 Runoff from the roof and terraces will be routed to the proposed cistern.
- Landscaped areas provide significant infiltration and generally have a lower TSS loading compared to roadways, therefore landscape runoff is credited with 80 percent TSS removal.

As shown in **Figure 3**, there is no driveway or loading area draining to the cistern. It is not expected that the site will contribute any contaminants to stormwater runoff, therefore there is no requirement for an Oil Grit Separator to meet the City requirements.

4.3 Quantity Control

4.3.1 Target Release Rate

Calculations using a Runoff Coefficient of 0.50 were used to determine the target flows form the site, as outlined in **Section 3.1**.1. The allowable peak release rate for the site is outlined in **Table 1**.

4.3.2 Quantity Control Measures

The following options were considered for quantity control on site:

Rooftop Storage – Controlled flow roof drains could be installed on the rooftop and water could be stored on the rooftops to attenuate peak flows. With typical flat rooftop design, flows can generally be limited to approximately 42L/s/ha. Rooftop storage is not counted for the quantity controls for the site, based on the proposed development.

Underground Storage – A restrictor pipe would be provided at the site outlet; with surplus storage provided in the cistern.

In order to meet the target release rates, cistern storage is proposed to provide quantity control for the proposed development, as follows.

Controlled Site Drainage

In the 100-year event, the required storage volume required to control the flows to meet the 12.8L/s target is approximately 23m^3 . Given that pipes and structures would provide a negligible amount of storage, and surface storage cannot be utilized, the cistern would be needed to provide all of the required storage. Approximately 30m^3 of storage is estimated to be provided above the outlet of the proposed cistern – details will be finalized in the detailed design stage of the project.

The summary table following shows the proposed flows for the site outletting to the Lakeshore Road East storm sewer. The majority of flow is captured and routed through the building's mechanical drainage system to the cistern, so that the affected area is controlled to meet the target release rate. The controlled flow will be provided by an ICD at the downstream end of the cistern.

Table 2. Site Quantity Control – Drainage to Lakeshore Road East

Catchment Name	Area (m²)	Runoff Coefficient (C)	Storage Required (m³)	100 Year Peak Flow (L/s)
Controlled Area (200)	821	0.84	23	8.0
Uncontrolled Area (201)	109	0.90	-	4.2
Total				12.3

Given the location of the cistern in the basement, it will be feasible to convey the controlled flows to the control MH by gravity. The details will be coordinated with the mechanical engineer in the detailed design stage of the project.

As shown, the proposed development flows for all the storm events meets the target flow, and the proposed flows will be conveyed underground for events up to 10-year storm event. Detailed calculations can be referenced in **Appendix B**. Refer to **Drawing C-101** for details of the proposed servicing for the site.

5.0 WASTEWATER

According to the As Constructed drawings for Ann Street and Lakeshore Road East provided by the City, there is a 250mm diameter sanitary sewer along Ann Street, and a 300mm diameter sanitary sewer along Lakeshore Road adjacent to the site. There is a control MH provided at the property line, connected to the 250mm main sewer on Ann Street by a 150mm diameter sewer, that can service the development.

The anticipated flows from the proposed development have been estimated based on the proposed design, for use by the Region to review the receiving system. Detail of the proposed sanitary connection is shown on **Drawing C-101**.

Based on the single-use demand table included in Appendix C, the sanitary flow from the site is estimated to be 1.62L/S, assuming 119 persons at the proposed site. The existing 250mm sanitary sewer service is capable of conveying this flow.

6.0 WATER DISTRIBUTION

According to the As Constructed drawings for Lakeshore provided by the City, a 300mm diameter watermain has been installed along the northern and eastern side of the right-of-way, adjacent to the site.

A fire flow test has been completed, with the results shown in **Appendix D**.

The following water usage parameters were used to determine the daily water demands for the proposed building as per Region Standards.

Estimated population = 119

• Water Demand = 270 Liters/cap/day

Peak Hour Peaking Factor = 3.0
 Maximum Day Peaking Factor = 1.8

Required minimum fire flow = Estimated using the Fire Underwriters Survey

Using the water usage parameters mentioned above the maximum daily flows and peak hourly flows for the proposed building was determined, as shown in **Table 4** below.

Table 3. Water Demand Summary

	Bldg Demand
Scenario	(L/s)
Max Day	0.67
Peak Hour	1.11
Max Day with Fire Flow	383.3

Based on the hydrant flow test conducted by L&D Waterworks on October 8th, 2021, the available fire flow at 20psi is approximately 624L/s (9,886gpm). Therefore, there is sufficient flow to service the site based on Region of Peel standards. The Single Use Demand Table can be referenced in **Appendix C**, while the FUS and hydrant flow test results can be seen in **Appendix D**.

7.0 EROSION AND SEDIMENT CONTROL

The erosion and sediment control plan will be prepared following the <u>Erosion and Sediment Control Guidelines for Urban Construction (ESC Guidelines)</u>, prepared by The Greater Golden Horseshoe Area Conservation Authorities, December 2006. The plan will be designed to limit sediment and debris from leaving the site during all stages of construction.

The sediment control plan for this site will generally consist of the following:

- A sediment control fence will be installed along the perimeter of the site where the grade will direct flows off-site.
- Site access will be limited to one entrance per phase of construction. A gravel access pad will be installed for staging of construction material and vehicles.
- Any mud tracked from the site should be swept immediately and a sweeper truck should be used as necessary to remove any additional debris.
- Trucks leaving the site should be covered with tarpaulin.
- During dry weather, above freezing construction periods, dust control measures including wetting the site and egress points should be implemented on an as needed basis.
- Once the storm sewer system has been constructed, catchbasin sediment control and protection devices will be installed and maintained until the site is ready to be paved.

Erosion measures will be in place prior to any grading on the site. A program will be in place to monitor and maintain the erosion and sediment controls. The sediment controls will be inspected by the Site Engineer and contractor:

- Once every 7 days and/or
- Within 24 hours following any significant rainfall event or snowmelt.

The inspection frequency can be extended to monthly inspections if there is no construction activity on-site. A detailed erosion and sediment control plan will be completed as part of the SPA submission.

8.0 CONCLUSIONS

The stormwater management design for the site has been designed to meet the criteria outlined by the City and the MECP Guidelines. The plan will consist of the following:

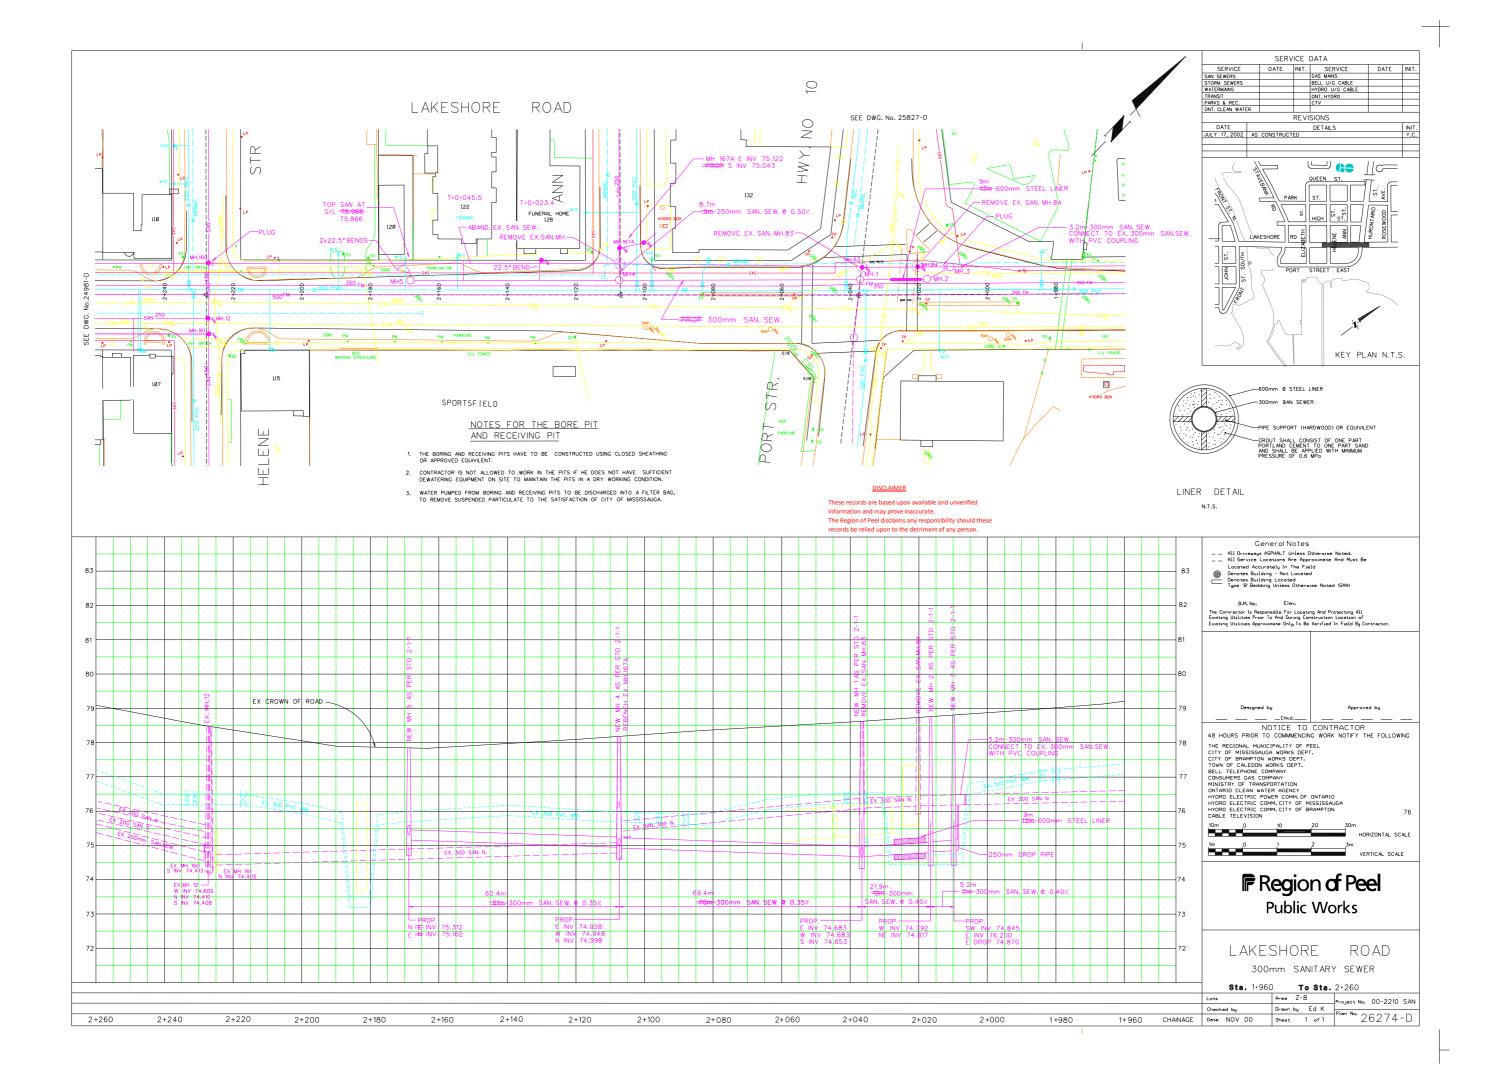

- The water balance targets for the proposed development will be achieved through the proposed landscape areas and proposed water re-use from the proposed cistern. Best efforts will be made to meet the City's requirements.
- The quality control requirements for the site can be addressed through a combination of the roof and other on-site landscape measures, which meets the City standard for 80 percent overall TSS removal.

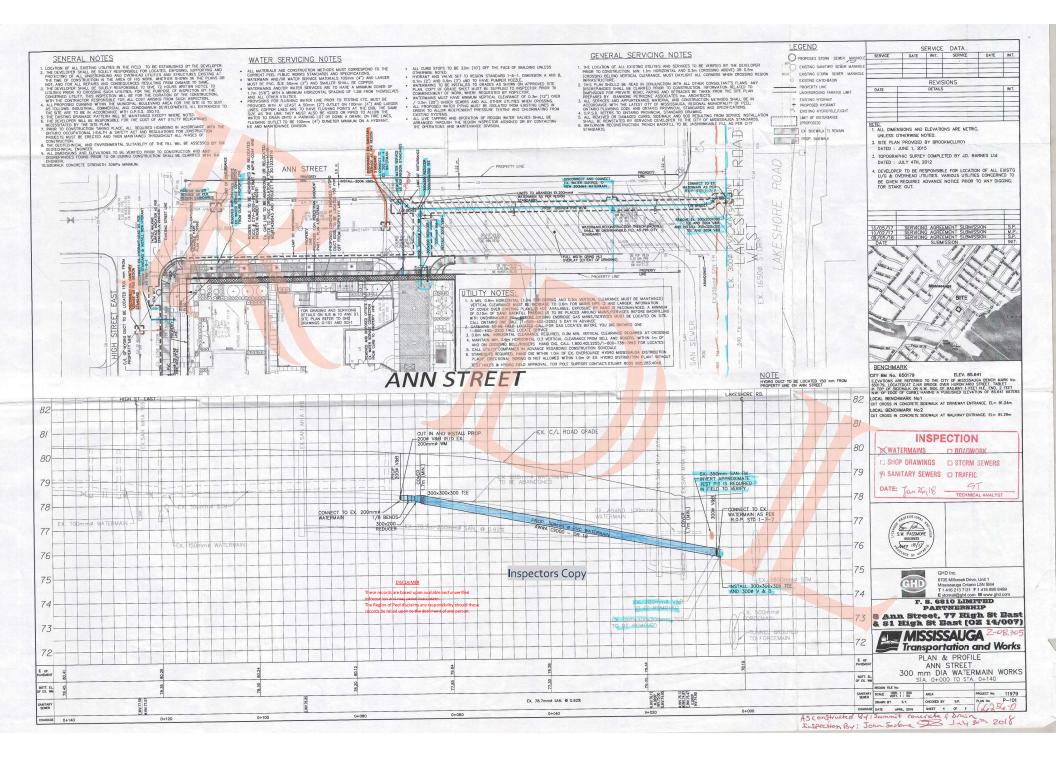

- Peak flows for storms up to and including the 100-year event will be controlled on site to meet the 10-year event with a Runoff Coefficient of 0.5. The proposed development will not have an adverse impact on the existing storm sewer system downstream of the site.
- Sanitary drainage will be conveyed to the existing 250mm diameter sanitary sewer on Ann Street, as per the Region requirements.
- Internal water distribution mains will be connected to the existing watermain located on Ann Street. A hydrant flow test has been completed, and the existing system provides sufficient flows to meet the requirements of the proposed development.

Therefore, based on the information provided herein, the stormwater management and site servicing requirements for the Site Plan Approval have been provided.

Water and Wastewater Modelling Demand Table

Site Plan Applications

Version	Date	Description of Revision
1.0	January 10 2023	Posted to Peel Website
2.0	August 30 2024	Reflects 2023 Linear Wastewater Standards and ICI population estimates as per Peel 2020 DC background study

Introduction

Water and wastewater modelling may be required as a condition of the development approval process or prior to regional site servicing connection approval where intensification is proposed, where a possible increase in water demand or wastewater discharge is identified or where deemed necessary by Regional staff.

A completed table includes the Professional Engineer's signature and stamp as well as a site servicing concept. The table will be deemed complete once all the information below is submitted and/or included. Modelling will commence once the information is deemed complete. All required calculations must be submitted with the completed demand table. The calculations shall be based on the specific development proposal.

28	Proposed additional effluent 8)		
29	Other proposed effluent*		
30	Total proposed effluent		

*Please specify other proposed effluent (ex. occasional tank purges, off peak discharge, poo
drainage)

Wastewater calculations

Please use the following updated daily per capita as per 2023 Peel Linear Wastewater Standards

Population Type	Unit	Average Day Demand	Min Peaking Factor	Max Peaking Factor	Inflow and Infiltration**
Residential	L/cap/d	290	2	4	0.26L/s/Ha
Non-residential	L/emp/d	270	2	4	0.26L/s/Ha

**For maintenance holes that are flood prone or located in low lying areas, an extra 0.28 L/s per maintenance hole may be added to the I&I calculation.

Notes

- In accordance with Peel Linear Wastewater Standards and Region of Peel 2020 DC background Study
- 2) refer to Peel Linear Wastewater Standards
- 3) For the commercial and industrial design flow calculations, please refer to Schedule 8b on page A-9 of the Region of Peel 2020 DC background Study to determine population.
- 4) Please include the graphs associated with the hydrant flow test data. Hydrant flow tests should be performed within 2 years of submission to the Region. The Region will not permit hydrant flow tests during the winter, please contact Region Water Operations for scheduling. The Region reserves the right to request an updated hydrant flow test as required at any time.
- 5) Please reference the Fire Underwriters Survey Document
- 6) Please identify the flows for each use type, if applicable
- 7) Please include drainage plan for multiple discharge locations
- 8) For Intensification, sites with additions to buildings or additional buildings please provide existing flow for existing buildings and the added flows for the new proposal, **if applicable**

Fire Flow Requirements

Project: 128 Lakeshore Road East

Project No.: 211246 Municipality: Mississauga

GUIDE FOR DETERMINATION OF REQUIRED FIRE FLOW

(as per the Water Supply for Public Fire Protection 1999 manual by the Fire Underwriters Survey)

STEP 1

Determine the fire flow.

Required Fire Flow (F) $F = 220 \times C \times \text{sgrt}(A)$ The required fire flow in litres per minute.

Maximum Floor Area (A) = 28376.1 m2 The total floor area in square metres (including all storeys, but excluding basements at

least 50% below grade) in the building being considered.

Coefficient (C) = 0.6 Coefficient related to the type of construction.

= 1.5 for wood frame construction (structure essentially all combustible).

= 1.0 for ordinary construction (brick or other masonry walls, combustible floor

= 0.8 for non-combustible construction (unprotected metal structural)

= 0.6 for fire-resistive construction (fullyprotected frame,floors, roof).

F = 22300 L/min.

STEP 2

Determine the increase or decrease for occupancy.

U%

Decrease 0 L/min.

Reduction for Low Hazard Occupancy (Dwellings).

STEP 3

Determine the decrease, if any, for automatic sprinkler protection.

50%

Decrease 11150 L/min.

STEP 4

Determine the total increase for exposures (Not to Exceed 75%).

west (15m)	15%	0 to 3m - 25% Increase	
north (22m)	10%	3.1 to 10m - 20% Increase	
east (30m)	10%	10.1 to 20m - 15% Increase	
South (7m)	20%	20.1 to 30m - 10% Increase	
	55.0%	30.1 to 45m - 5% Increase	
Increase	12265 L/min.	Greater then 45m - No Increase	

STEP 5

Determine the minimum required fire flow.

F = 390.25 L/s

Fire Flow Calculation

Project: 128 Lakeshore Road East

Project No.: 211246 Municipality: Mississauga

GUIDE FOR CALCULATING CAPACITY AT 20psi FOR FIRE FLOW

(as per the NFPA 291: Recommended Practice for Fire Flow Testing and Marking of Hydrants. (2010). (Section 4.10.1.2.))

The Formula for Calculating Rated Capacity at 20psi

 $Q_R = Q_F x (H_R / H_F)^{0.54}$

Where:

Q_R = Rated Capacity at 20psi (in GPM)

Q_F = Total test flow (in GPM)

H_R = Static Pressure minus 20 psi

H_F = Static Pressure minus Residual Pressure

Based on hydrant flow test by L&D

Flow Test Parameters: Waterworks, dated Oct 8, 2021.

Static Pressure 88.0 psi

Residual Pressure 86.0 psi

Test Flow Rate 1472 GPM

 $Q_R = \frac{1472 \text{ x ((}}{88.0 \text{ psi - 20) / (}} \frac{88.0 \text{ psi - }}{6.0 \text{ psi)}}^{0.54}$

Q_R = 9883 GPM

37,413 L/min

Hydrant Flow Test Report

SITE NAME: TEST DATE:
SITE ADDRESS / MUNICIPALITY: 128 Lakeshore Road East, Mississauga October 08,2021

TEST HYDRANT LOCATION : Northeast Corner of Lakeshore Road, East at

Ann Street

BASE HYDRANT LOCATION: 1st Fire Hydrant East of Hurontario Street on
Lakeshore Road East

TEST BY: Luzia Wood

TEST DATA
